

PRODUCT MONOGRAPH
INCLUDING PATIENT MEDICATION INFORMATION

OCTAPLASMA™

Solvent Detergent (S/D) Treated Human Plasma

Prescription medication, Plasma Substitute: Blood Plasma, solution for intravenous infusion

Liquid: 200 mL

ATC-Code: B05AX03

Manufactured by:
Octapharma AB
Lars Forssells gata 23
112 75 Stockholm, Sweden

Date of Initial Authorization:
AUG 11, 2005

Date of Revision:
October 31, 2022

Manufactured for:
Octapharma Canada Inc.
1000-25 King St W
Toronto, ON M5L 1G1
Canada

Submission Control Number: 267497

PART I: HEALTH PROFESSIONAL INFORMATION

1 INDICATIONS

OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) is indicated for:

- Complex deficiencies of coagulation factors such as consumption coagulopathy e.g. disseminated intravascular coagulation (DIC) or coagulopathy due to severe hepatic failure, massive transfusion, or repeated large volume plasma exchange (especially in patients with impaired liver function).
- OCTAPLASMA may be used for emergency substitution therapy in coagulation factor deficiencies, when situations, e.g. haemorrhage, do not allow a precise laboratory diagnosis, or when a specific coagulation factor concentrate is not available.
- Rapid reversal of effects of oral anticoagulants when vitamin K is insufficient in emergency situations, or in patients with impaired liver function.

The efficacy in patients with Thrombotic Thrombocytopenic Purpura has not been studied sufficiently, therefore, the clinical experience in these patients is limited.

OCTAPLASMA should be administered under the supervision of a qualified health professional who is experienced in the use of anticoagulation agents and in the management of coagulation disorders. Appropriate management of therapy and complications is only possible when adequate diagnostic and treatment facilities are readily available.

1.1 Pediatrics

Pediatrics (< 20 years of age): OCTAPLASMA was evaluated in 91 pediatric patients (age range 0-20 years) in two post-marketing studies. (See CLINICAL TRIALS, Table 7). The product should only be administered to these individuals if the likely benefits clearly outweigh potential risks.

1.2 Geriatrics

No data are available.

2 CONTRAINDICATIONS

Contraindications for OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) are as follows:

- OCTAPLASMA is contraindicated in patients with IgA deficiency with documented antibodies against IgA as it may cause anaphylactic and anaphylactoid reactions.
- OCTAPLASMA is contraindicated in patients with severe deficiency of protein S as it may result in an increased risk of developing blood clots.
- OCTAPLASMA is contraindicated in patients who are hypersensitive to this drug or to any ingredient in the formulation, including any non-medicinal ingredient, or component of the container. For a complete listing, see [6 DOSAGE FORMS, STRENGTHS, COMPOSITION AND PACKAGING](#).

3 SERIOUS WARNINGS AND PRECAUTIONS BOX

Serious Warnings and Precautions

- This product is prepared from large pools of human plasma, which may contain the causative agents of hepatitis and other viral diseases. The physician should discuss the risks and benefits of this product with the patient before prescribing or administering to the patient (see [WARNINGS AND PRECAUTIONS - General](#)).

4 DOSAGE AND ADMINISTRATION

4.1 Dosing Considerations

The dosage depends upon the clinical situation and underlying disorder. The volume and frequency of plasma exchanges vary depending on the individual patient, the clinical situation, and the preferred regimen of treatment. In the event of major haemorrhage or surgery, the expert advice of a haematologist should be sought.

High dosages or infusion rates may induce hypervolaemia, pulmonary oedema and/or cardiac failure. High infusion rates may cause cardiovascular effects as a result of citrate toxicity (fall in ionised calcium), especially in patients with liver function disorders. Due to the risk of citrate toxicity, the infusion rate should not exceed 0.020-0.025 mmol citrate/kg body weight/min, which equals to 1 mL OCTAPLASMA/kg body weight/min. Toxic effects of citrate can be minimised by giving calcium gluconate i.v. into another vein. Patients should be observed for at least 20 minutes after the administration.

4.2 Recommended Dose and Dosage Adjustment

The volume and frequency of plasma exchanges vary depending on the individual patient, the clinical situation, and the preferred regimen of treatment. The volume of the plasma exchange in most therapeutic procedures is usually equivalent to the plasma volume of the patient. A part of the exchanged plasma volume should be replaced with OCTAPLASMA in order to prevent haemostatic disorders associated with a decreased level of coagulation factors (especially in patients with impaired liver function).

The dosage depends upon the clinical situation and underlying disorder, but 12-15 mL OCTAPLASMA/kg body weight is a generally accepted starting dose (this should increase the patient's plasma coagulation factor levels by approximately 25%). It is important to monitor the response, both clinically and with measurement of prothrombin time (PT), partial thromboplastin time (PTT) and/or specific coagulation factor assays.

An adequate haemostatic effect in minor and moderate haemorrhages or surgery is normally achieved after the infusion of 5-20 mL OCTAPLASMA/kg body weight (this should increase the patient's plasma coagulation factor levels by approximately 10-33%). In the event of major haemorrhage or surgery the expert advice of a haematologist should be sought.

4.4 Administration

Administration of OCTAPLASMA must be based on ABO-blood group specificity. In emergency cases, OCTAPLASMA blood group AB can be regarded as universal plasma since it can be given to all patients. OCTAPLASMA must be administered by intravenous infusion after thawing using an infusion set with a filter. Aseptic technique must be used throughout the infusion.

There are several options for thawing frozen OCTAPLASMA:

- Using a water bath:

Thaw in the outer wrapper for not less than 30 minutes in a circulating water bath at +30 °C to +37 °C. An overwrap bag may be used to provide further protection of contents if appropriate. Prevent water from contaminating the entry port. The minimum thawing time is 30 minutes at 37 °C. Temperature in the water bath must never exceed +37 °C and should not be lower than +30 °C. The thawing time depends on the number of bags in the water bath. If more plasma bags are thawed in parallel, the thawing time can be prolonged, but should not be longer than 60 minutes.

- Using a dry tempering system such as the SAHARA-III:

Place the OCTAPLASMA bags on the agitation plate according to the manufacturer instructions and thaw plasma using the fast tempering function. When +37 °C blood component temperature is indicated on the temperature display terminate the tempering process and remove the bags.

During thawing of plasma using a system such as the SAHARA-III tempering system it is recommended to use the protocol printer to record the course of the blood component temperature and error messages in event of failure.

Other thawing systems for frozen OCTAPLASMA can be used on the condition that the methods are validated for that purpose.

Allow the content of the bag to warm to approximately +37 °C before infusion. The temperature of OCTAPLASMA must not exceed +37 °C. Remove the outer wrapper and examine the bag for cracks or leaks.

Avoid shaking.

Do not use solutions that are cloudy or have deposits.

Precautions:

Interactions with other drugs are unknown. OCTAPLASMA must not be mixed with other drugs as inactivation and precipitation may occur. To avoid the possibility of clot formation, solutions containing calcium must not be administered by the same intravenous line as OCTAPLASMA.

Due to the risk of activation/inactivation of OCTAPLASMA, the concomitant administration of other blood products should be avoided as much as possible, except for emergency situations. However, the product can be mixed with red blood cells and platelets.

Special Precautions for Storage:

Protect from light.

Thawed OCTAPLASMA must not be refrozen. Unused product must be discarded.

4.5 Missed Dose

Not applicable because OCTAPLASMA is administered in a hospital setting by health care professionals.

5 OVERDOSAGE

Overdose may lead to hypervolaemia and thereby pulmonary oedema and/or cardiac failure. In such cases, OCTAPLASMA transfusion should be stopped immediately. General measures such as the administration of furosemide can be considered, if clinically appropriate.

For management of a suspected drug overdose, contact your regional poison control centre.

6 DOSAGE FORMS, STRENGTHS, COMPOSITION AND PACKAGING

To help ensure the traceability of biologic products, including biosimilars, health professionals should recognise the importance of recording both the brand name and the non-proprietary (active ingredient) name as well as other product-specific identifiers such as the Drug Identification Number (DIN) and the batch/lot number of the product supplied.

Table – Dosage Forms, Strengths, Composition and Packaging

Route of Administration	Dosage Form / Strength/Composition	Non-medicinal Ingredients
Injection	Solvent Detergent (S/D) Treated Human Plasma Per 200 mL: Human plasma proteins 9.0-14.0 g (45-70 mg/mL)	Glycine Octoxynol Sodium citrate dihydrate, Sodium dihydrogenphosphate dihydrate TNBP

OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) is supplied frozen in bags of 200 mL containing 45-70 mg/mL Human Plasma Proteins.

Nature and Contents of Container:

Each 200 mL of OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) contains Human plasma proteins (9.0-14.0 g), Sodium citrate dihydrate (0.88-1.48 g), Sodium dihydrogenphosphate dihydrate (0.06-0.24 g), Glycine (0.80-1.20 g), TNBP (< 2.0 mcg/mL), Octoxynol (< 5.0 mcg/mL).

7 WARNINGS AND PRECAUTIONS

Please see [3 SERIOUS WARNINGS AND PRECAUTIONS BOX](#).

This product is prepared from large pools of human plasma. Thus, there is a possibility it may contain causative agents of viral or other undetermined diseases.

General

Products made from human plasma may contain infectious agents, such as viruses, that can cause disease. The risk that such products will transmit an infectious agent has been reduced by screening plasma donors for prior exposure to certain viruses, by testing for the presence of certain current virus infections, and by inactivating and/or removing certain viruses. Individuals who receive infusions of blood or plasma products may develop signs and/or symptoms of some viral infections.

When medicinal products prepared from human plasma are administered, infectious disease due to the transmission of infective agents cannot be totally excluded. Like other plasma products, OCTAPLASMA carries the possibility for transmission of blood-borne viral agents, and theoretically, the variant Creutzfeldt-Jakob disease (vCJD) agent. This applies also to pathogens of hitherto unknown origin.

To reduce the risk of transmission of infective agents, stringent controls are applied to the selection and screening of donors for hepatitis B, hepatitis C and HIV infection. The plasma pools are also tested for HBsAg, anti-HIV 1/2, HBV-NAT, HIV-NAT, HCV-NAT, HAV-NAT, HEV-NAT and parvovirus B19-NAT and only those found negative or below a given cut-off limit (parvovirus B19) are used for manufacturing.

S/D treatment is not effective against non-enveloped viruses, including parvovirus B19 and HAV.

Transmission of HAV may occur following transfusion with OCTAPLASMA. It is, however greatly reduced by accepting only plasma pools found negative for HAV by a NAT test and by the presence of justified limits for neutralizing antibodies towards HAV.

Transmission of parvovirus B19 may occur following transfusion of OCTAPLASMA. However plasma pools are tested for the presence of justified limits for neutralizing antibodies towards parvovirus B19 and the parvovirus B19–NAT. This combination may limit the risk of infection, although no laboratory or clinical studies have been performed to show that it is sufficient to prevent infection.

However, as with FFP, the transmission of parvovirus B19 or HAV by OCTAPLASMA cannot be totally excluded. In immunocompromised patients, in patients with haematological disorders of high red cell turnover and in pregnant women, parvovirus B19 infections could lead to aplastic crises and hydrops fetalis with subsequent foetal loss, respectively. Therefore, OCTAPLASMA should only be administered to these patients if strongly indicated. A possible risk of infection should be weighed against the benefit of the inactivation of enveloped viruses such as HIV, HBV and HCV. Appropriate vaccination (e.g. against HAV) for patients in regular receipt of OCTAPLASMA should be considered. Infusion of OCTAPLASMA may give rise to specific coagulation factor antibodies.

Five cases of possible transmission of vCJD, or the causative agent of this disease, by non-leukocyte-depleted red blood cell concentrates (n=4) and a low-purity coagulation factor concentrate to a haemophiliac (n=1) have been reported in the literature. The possibility of transmission of the vCJD agent by S/D plasma cannot be completely ruled-out. At present, the vCJD agent cannot be routinely detected in blood. However, the hypothesis of the B-lymphocytes and follicular dendritic cells, in particular, acting as potential blood borne carriers of the prion protein and their role in neuroinvasion, suggests that leukocyte depletion during processing of blood products and plasma-derivatives will reduce the possibility of transmitting vCJD. Thus, leukocyte depletion of cellular blood components has been adopted by some countries as a measure to reduce the hypothetical risk of vCJD transmission. OCTAPLASMA undergoes multiple size exclusion filtration steps resulting in complete leukocyte removal without activating the leukocytes, and both this particular measure and the down-stream processing have demonstrated a potential to clear prions using an animal model of the agent causing vCJD. Additionally, a column has been included into the production process of OCTAPLASMA in order to specifically remove prions. This safety measure is considered effective for removing the infectious agent causing vCJD, if present in plasma. No animal material is used in the production of OCTAPLASMA.

Individuals who receive infusion of blood or plasma products may develop signs and/or symptoms of some viral infections. In the interest of the patient, it is recommended that, whenever possible, every time that OCTAPLASMA is administered to them, the name and batch number of the product is recorded.

Cardiovascular

High dosages of OCTAPLASMA or high infusion rates may induce hypervolaemia, pulmonary oedema, and/or cardiac failure. OCTAPLASMA should be used with caution in patients with pulmonary oedema, and manifest or latent cardiac decompensation. High infusion rates may cause symptoms attributable to citrate toxicity (fall in ionised calcium) e.g. fatigue, paresthaesia, tremor and hypocalcaemia, especially in patients with liver function disorders.

Gastrointestinal

The infusion should be discontinued if subjective complaints (e.g. nausea) cannot be mitigated by a reduction of the infusion rate.

Hematologic

OCTAPLASMA should not be used to correct hyperfibrinolysis caused by a deficiency of the plasmin inhibitor, alpha2-antiplasmin, as dilution with S/D treated plasma (which contains low levels of alpha2-antiplasmin) may further reduce alpha2-antiplasmin levels. Special attention must be paid to signs of excessive bleeding tendency in patients likely to require massive transfusions e.g. in liver transplantation or other conditions with complex disturbances of haemostasis.

An increased incidence of thromboembolic events has been described in patients receiving large volumes of S/D treated plasma. In patients considered at risk for such complications, OCTAPLASMA should only be used if the benefit exceeds the risk of thromboembolic events. Appropriate protection against thromboembolism should be employed when indicated, and patients should be monitored for thromboembolic events.

In extensive plasma exchange procedures, OCTAPLASMA should only be used to correct the coagulation abnormality when abnormal haemorrhage occurs.

Immune

Administration of OCTAPLASMA must be based on ABO-blood group specificity, otherwise incompatibility reactions between antibodies contained in OCTAPLASMA and antigens on the recipient's red blood cells can result in immediate or delayed type haemolytic transfusion reactions.

OCTAPLASMA should be used with caution in patients with IgA deficiency, plasma protein allergy or previous reaction to FFP or OCTAPLASMA.

In case of anaphylactic reaction or shock, the infusion must be stopped immediately. Treatment should follow the guidelines for shock therapy.

Monitoring and Laboratory Tests

It is important to monitor the response of the patients coagulation factor levels, both clinically and with measurement of prothrombin time (PT), partial thromboplastin time (PTT) and/or specific coagulation factor assays.

7.1 Special Populations

7.1.1 Pregnant Women

The safety of OCTAPLASMA for use in human pregnancy and during lactation has not been established in controlled clinical trials.

A study of the embryotoxic and teratogenic properties of TNBP and Octoxynol was carried out in rats and rabbits at dose levels of 50 to 900 µg/kg BM/day for TNBP and 250 to 4,500 µg/kg BM/day for Octoxynol. No test was made of the fertility and breeding efficiency, or the peri- and post-natal development since there was no evidence of any effect on the reproductive organs by the substances. In rats, some malformations occurred, but these were of a type commonly occurring in control animals of this species. No malformations were seen in the rabbits. Pre-natal development was not affected in the rats, although in the high-dose group in the rabbit, the resorption rate was slightly increased and body weight of the foetus was moderately and significantly decreased.

Although no harmful effects on mother, embryo, foetus, or child are to be expected, OCTAPLASMA should be used during pregnancy and lactation only if the benefit outweighs the potential risk.

7.1.2 Breast-feeding

It is unknown if OCTAPLASMA is excreted in human milk. Precaution should be exercised because many drugs can be excreted in human milk.

7.1.3 Pediatrics

OCTAPLASMA was evaluated in 91 pediatric patients (age range 0-20 years) in two post-marketing studies. The product should only be administered to these individuals if the likely benefits clearly outweigh potential risks.

7.1.4 Geriatrics

No data are available.

8 ADVERSE REACTIONS

8.1 Adverse Reaction Overview

High dosages of OCTAPLASMA or increased infusion rates may induce hypervolaemia, pulmonary oedema and/or cardiac failure. In the course of plasma exchange, symptoms attributable to citrate toxicity (e.g. fatigue, paresthaesia, tremor and hypocalcaemia) may occur.

Administration of OCTAPLASMA must be based on ABO-blood group specificity, otherwise incompatibility reactions between antibodies contained in OCTAPLASMA and antigens on the recipient's red blood cells can result in immediate or delayed type haemolytic transfusion reactions.

Transfusion-related acute lung injury (TRALI), which is a severe and rather frequent adverse reaction known from the use of FFP, has not been observed with OCTAPLASMA.

The following adverse reactions have not been reported with OCTAPLASMA but were observed with FFP and therefore may also occur with OCTAPLASMA:

- Rarely (<1/1000), potent anti-leukocyte antibodies may be present which, as a consequence of leukocyte aggregation in pulmonary vessels, can provoke an acute pulmonary injury, a syndrome known as transfusion related acute lung injury characterized by chills, fever, a non-productive cough, and dyspnea.

- Rarely (<1/1000), potent specific platelet antibodies may be present which can induce a passive post-transfusion purpura (PTP) characterized by dyspnea, rash, fever, generalized purpura, and marked thrombocytopenia.

Management of Severe Adverse Reactions

The infusion should be discontinued if subjective complaints (e.g. nausea) cannot be mitigated by a reduction of the infusion rate. In case of skin reactions or tachycardia accompanied by a drop in blood pressure, or in case of respiratory problems with or without shock, infusion should be stopped immediately.

In Table 1 the different measures are specified for the different clinical symptoms.

Table 1: Symptoms and Treatment of Adverse Reactions

Clinical Symptoms	Emergency Measures
Subjective complaints (nausea, etc.)	Reduce infusion rate; if unsuccessful stop administration until recovery.
Skin symptoms (flush, urticaria, etc.)	Stop administration. Administer antihistamines intravenously.
Tachycardia Moderate drop in blood pressure (below 90 mm Hg systolic)	Stop administration. Administer hydrocortisone i.v.
Dyspnoea Shock	Stop administration. Administer adrenaline (epinephrine) s.c. or i.m.; hydrocortisone i.v.; oxygen, volume expander; possibly increase diuresis using furosemide in case of normovolaemia, control of acid base balance; if necessary correct electrolytes.
Persistent normovolaemic shock	Dopamine hydrochloride, possibly in combination with noradrenaline (norepinephrine).
Cardiac or respiratory arrest	Resuscitation.

The following guidance (see Table 2) applies to specific adverse reactions, which may be associated with OCTAPLASMA:

Table 2: Guidance for Specific Adverse Reactions

Clinical symptoms	Emergency measures
Citrate toxicity (fall in ionised calcium)	Reduce infusion rate or stop administration until recovery. Calcium gluconate 10% i.v. at a dose of 10 mL/L OCTAPLASMA infused.
Haemolytic transfusion reaction	Stop administration. Increase diuresis (maintain urine flow rates above 100 mL/hour in adults for at least 18-24 hours) using i.v. electrolytes and mannitol (e.g. mannitol 15%, 125 mL/hour) or furosemide, sodium bicarbonate; dialysis in case of anuria. If applicable, symptomatic treatment of shock.

8.2 Clinical Trial Adverse Reactions

Clinical trials are conducted under very specific conditions. The adverse reaction rates observed in the clinical trials; therefore, may not reflect the rates observed in practice and should not be compared to the rates in the clinical trials of another drug. Adverse reaction information from clinical trials may be useful in identifying and approximating rates of adverse drug reactions in real-world use.

Six clinical studies with OCTAPLASMA have been conducted by Octapharma. In total, 229 patients have been enrolled, and the patients were exposed to a total number of about 1,200 treatment courses with OCTAPLASMA.

For a comprehensive overview of all clinical studies performed with OCTAPLASMA please refer to Table 7 under PART II: [CLINICAL TRIALS](#).

Relative Frequency of Adverse Drug Reactions

The frequency of adverse drug reactions observed in clinical studies is shown in Table 3 below. The safety information derives from about 230 patients enrolled in 6 clinical studies.

Table 3: Overview of OCTAPLASMA Adverse Reactions Observed in Clinical Studies

System Organ Class	Common (> 1/100 <1/10)	Uncommon (> 1/1000 <1/100)
Immune system disorders		anaphylactic reaction
Metabolism and nutrition disorders		hypocalcaemia
Nervous system disorders		paraesthesia
Vascular disorders		hypotension
Respiratory, thoracic and mediastinal disorders		bronchospasm cough respiratory arrest or failure
Gastrointestinal disorders	nausea	vomiting
Skin and subcutaneous tissue disorders	rash pruritus	urticaria
General disorders and administration site conditions	pyrexia chills	oedema

8.3 Less Common Clinical Trial Adverse Reactions

Please refer to Table 3 above.

8.4 Abnormal Laboratory Findings: Hematologic, Clinical Chemistry and Other Quantitative Data

High infusion rates may cause symptoms attributable to citrate toxicity (fall in ionised calcium) e.g. hypocalcaemia, fatigue, paresthesia, and tremor, especially in patients with liver function disorders.

OCTAPLASMA contains low levels of alpha2-antiplasmin and should therefore not be used to correct hyperfibrinolysis caused by a deficiency of the plasmin inhibitor. Special attention must be paid to signs of excessive bleeding tendency in patients likely to require massive transfusions e.g. in liver transplantation or other conditions with complex disturbances of haemostasis.

8.5 Post-Market Adverse Reactions

Since the introduction of OCTAPLASMA in Europe in 1992, more than 11.8 million units of OCTAPLASMA have been infused into approximately 3.9 million patients. For more detailed information of reported adverse reactions please refer to Table 4.

Table 4 provides an overview on ADRs that have rarely been reported during the use of OCTAPLASMA during its post-approval use. As these reactions are reported voluntarily from a population of uncertain size, a reliable estimation of frequency cannot be established.

Table 4 : Adverse Reactions that were reported for OCTAPLASMA during its Post-Marketing Use

System Organ Class	Reaction
Blood and lymphatic system disorders	haemolytic anaemia
Immune system disorders	anaphylactic shock anaphylactic reaction anaphylactoid reaction hypersensitivity
Metabolic and nutritional disorders	citrate toxicity alkalosis
Psychiatric disorders	Agitation
Cardiac disorders	cardiac arrest arrhythmia transfusion-related circulatory overload tachycardia
Vascular disorders	Thromboembolism circulatory collapse hypertension hypotension flushing haemorrhagic diathesis
Respiratory, thoracic and mediastinal disorders	pulmonary haemorrhage acute pulmonary oedema bronchospasm dyspnoea respiratory arrest or failure
Gastrointestinal disorders	vomiting nausea

System Organ Class	Reaction
Skin and subcutaneous tissue disorders	urticaria rash (erythematous) pruritus hyperhidrosis
General disorders and administration site conditions	chest pain chills pyrexia localised oedema application site reaction
Investigations	antibody test positive
Injury, poisoning and procedural complications	haemolytic transfusion reaction

9 DRUG INTERACTIONS

9.2 Drug Interactions Overview

No formal studies of drug interactions have been performed and interactions with other drugs are unknown.

OCTAPLASMA must not be mixed with other drugs as inactivation and precipitation may occur. To avoid the possibility of clot formation, solutions containing calcium must not be administered by the same intravenous line as OCTAPLASMA.

Due to the risk of activation/inactivation of OCTAPLASMA, the concomitant administration of other blood products should be avoided as much as possible, except for emergency situations. However, the product can be mixed with red blood cells and platelets.

OCTAPLASMA administration may impair the efficacy of live attenuated virus vaccines such as measles, mumps, rubella and varicella for at least six weeks, and possibly up to three months. In some cases, where large doses are given, this period may be as long as one year.

9.4 Drug-Drug Interactions

Interactions with other drugs have not been established. During clinical trials, OCTAPLASMA has been administered in association with various concomitant medications, and no interactions have been identified.

9.5 Drug-Food Interactions

Interactions with food have not been established.

9.6 Drug-Herb Interactions

Interactions with herbal products have not been established.

9.7 Drug-Laboratory Test Interactions

Passive transmission of plasma components from OCTAPLASMA (e.g. β -human chorionic gonadotropin; β -HCG) may result in misleading laboratory results in the recipient. For example, a false-positive pregnancy test result has been reported following passive transmission of β -HCG.

10 CLINICAL PHARMACOLOGY

10.1 Mechanism of Action

OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) is a virus inactivated frozen human plasma and is assumed to be active on a species-specific basis.

10.2 Pharmacodynamics

The total protein concentration is 45-70 mg/mL. The protein distribution is within the normal range of human plasma, please refer to Table 5 below. Protein S and Plasmin inhibitor levels have been found to be below the range for normal human plasma. The final product release limits are ≥ 0.4 IU/ml and ≥ 0.2 U/ml, respectively.

After S/D treatment and subsequent removal of S/D reagents, the plasma protein content and distribution in OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) remain at comparable levels to those in normal fresh frozen plasma (see Table 5).

Table 5: Plasma Protein Levels in OCTAPLASMA Compared to Single-Donor Fresh-Frozen Plasma

Parameters	OCTAPLASMA (n=12)	Reference ranges
	Mean (min-max)	FFP
Total protein [mg/mL]	55 (54-57)	48-64
Albumin [mg/mL]	32 (30-34)	28-41
Fibrinogen [mg/mL]	2.5 (2.4-2.6)	1.45-3.85
IgG [mg/mL]	9.65 (9.15-10.10)	6.60-14.50
IgA [mg/mL]	2.00 (1.80-2.05)	0.75-4.20
IgM [mg/mL]	1.25 (1.20-1.30)	0.40-3.10
Factor V [IU/mL]	0.78 (0.75-0.84)	0.54-1.45
Factor VII [IU/mL]	1.08 (0.90-1.17)	0.62-1.65
Factor X [IU/mL]	0.78 (0.75-0.80)	0.68-1.48
Factor XI [IU/mL]	0.99 (0.91-1.04)	0.42-1.44
Protein C [IU/mL]	0.85 (0.81-0.87)	0.58-1.64
Protein S [IU/mL]	0.64 (0.55-0.71)	0.56-1.68
Plasmin inhibitor [IU/mL]	0.23 (0.20-0.27)	0.72-1.32

12 consecutive batches OCTAPLASMA were investigated; mean (minimum-maximum) values are presented; FFP, single-donor fresh-frozen plasma

One clinical study aimed to investigate the pharmacodynamics of OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) has been performed.

Five male and six female patients, included for hereditary, acquired, isolated or combined coagulation deficiency, received lyophilised OCTAPLASMA as a single, i.v. injection. Thereof, 2 patients each had a factor VII or factor X, and 4 patients a factor XI deficiency. Two patients received OCTAPLASMA lyophilisate for ongoing bleeding, one for plasmapheresis and eight for prevention of bleeding before an invasive procedure. Bleeding was stopped in the two patients with ongoing bleeding. In the nine other patients, plasmapheresis and surgical procedures were uneventful, with no abnormal bleeding. The overall effectiveness of OCTAPLASMA as rated by the investigator was good in all patients.

Two patients experienced a total of three adverse events (AEs), consisting of an anaphylactoid reaction and urticaria with pruritus. These AEs resolved with an antihistaminic and both patients recovered. No patient dropped out of the study for safety reasons. No serious and/or unexpected AEs occurred. No adverse laboratory findings were observed for haematology, blood biochemistry and viral safety parameters.

10.3 Pharmacokinetics

During one clinical study pharmacokinetic data of coagulation factors after treatment with OCTAPLASMA reconstituted as lyophilisate have been collected from eight patients suffering from hereditary coagulation factor deficiencies. All patients received a single OCTAPLASMA infusion of an average of 580 mL (range 400 to 1,600 mL). The dose administered was expected to achieve and maintain a plasma concentration of 10% to 20% of normal of the deficient coagulation factor. The pharmacokinetic results are shown in Table 6.

Table 6: Pharmacokinetic results

Parameter (Unit)	FVII [range] (n=2)	FX [range] (n=2)	FXI [mean, range] (n=4)
Vd (mL/kg)	33 – 48	23 – 49	52 (45 – 57)
CL (mL/kg/h)	4.7 – 7.9	0.3 – 0.8	0.9 (0.6 – 1.3)

These pharmacokinetics parameters after OCTAPLASMA administration were within the kinetic profile of coagulation factors after administration of FFP. No pharmacokinetic results are available for the remaining coagulation factors.

Absorption

OCTAPLASMA is administered intravenously and therefore immediately available in the organism.

Distribution, Metabolism and Excretion:

OCTAPLASMA is a virus inactivated frozen human plasma and is assumed to be active on a species-specific basis. Human plasma may cause severe toxic reactions in animals and is not tolerated at dosages approaching those generally used in humans. Routine pharmacology testing in laboratory animals is not considered to add any relevant information for the safety and efficacy of OCTAPLASMA in the clinical use.

Two contaminants derived from the manufacturing process, namely Tri(n-butyl)phosphate (TNBP) and Octoxynol, might be present in the final product. A program of studies has been carried out to assess the pharmacokinetic profile of TNBP and Octoxynol. After i.v. administration in rats, TNBP disappeared rapidly from the plasma with an elimination half-life of approximately 20 min. TNBP was not found at any time in the urine and only very small amounts were detectable in the faeces. Concomitantly administered Octoxynol could not be detected in the plasma, the urine or the faeces.

Special Populations and Conditions

No specific pharmacokinetic studies have been performed in patients at increased risk, such as elderly subjects or patients with renal or hepatic impairment.

11 STORAGE, STABILITY AND DISPOSAL

The shelf life of OCTAPLASMA is 48 months when stored at ≤ -18 °C.

Protect from exposure to light.

After thawing, OCTAPLASMA can be stored for up to 5 days at +2-8 °C or for up to 8 hours at room temperature (+20-25°C) before use. Do not use solutions that are cloudy or have deposits.

Thawed OCTAPLASMA must not be refrozen. Unused product must be discarded.

12 SPECIAL HANDLING INSTRUCTIONS

Any unused product or waste material should be disposed of in accordance with local requirements for blood products.

PART II: SCIENTIFIC INFORMATION

13 PHARMACEUTICAL INFORMATION

Drug Substance

Proper name: OCTAPLASMA, Solvent Detergent (S/D) Treated Human Plasma

Chemical name: Human Plasma

Molecular formula and molecular mass: not applicable

Structural formula: not applicable

Physicochemical properties: The total protein concentration is 45-70 mg/mL. The protein distribution is within the normal range of human plasma.

Pharmaceutical standard: ATC-Code: B05AX03

Product Characteristics:

OCTAPLASMA is solvent detergent (S/D) treated human plasma (45-70 mg/mL human plasma proteins). During the manufacturing process, OCTAPLASMA is treated with a combination of 1 % Tri(nbutyl)- phosphate (TNBP) and 1 % Octoxynol. These S/D reagents are removed by castor oil extraction (TNBP) and subsequent solid phase extraction (Octoxynol) before sterile filtration. After sterile filtration, 200 mL OCTAPLASMA is filled into sterile, pyrogen-free, plasticised polyvinyl chloride (PVC) blood bags that are over-wrapped with a polyamide/polyethylene film.

The coagulation activity values are close to the corresponding values for normal human single-donor fresh-frozen plasma (FFP) and a minimum of 0.5 IU/mL is obtained for all clotting factors. However, as a result of the S/D treatment and purification, the content of lipids and lipoproteins is reduced. This is of no relevance for the indications for OCTAPLASMA. OCTAPLASMA has similar pharmacokinetic properties as normal FFP.

Viral Inactivation

Precautions against viral transmission include: selection of plasma donors, screening of donations and plasma pool, as well as quality control measurements of the final product. As with any blood product, a potential problem is the transmission of blood borne pathogens including those of hitherto unknown origin. When medicinal products prepared from human blood or plasma are given to a patient, the transmission of infectious agents cannot be totally excluded. This applies also to hitherto unknown pathogens. This product is prepared from large pools of human plasma, which may contain the causative agents of hepatitis and other viral diseases (see [WARNINGS AND PRECAUTIONS](#) section).

To reduce the risk of transmission of infective agents, stringent controls are applied to the selection and screening of donors for hepatitis B, hepatitis C and HIV infection. The plasma pools are also tested for HBsAg, anti-HIV-1/2, HBV-NAT, HIV-NAT, HCV-NAT, HAV-NAT, HEV-NAT and parvovirus B19-NAT and only those found negative or below a given cut-off limit (parvovirus B19) are used for manufacturing. To improve the viral safety of OCTAPLASMA compared to FFP, virus inactivation using the S/D method has been included in the OCTAPLASMA manufacturing process. The S/D method has been shown to inactivate the enveloped viruses (such as HIV, HBV and HCV) in a rapid and complete manner.

From its mode of action it is clear that the S/D method has no effect on non-enveloped viruses such as HAV and parvovirus B19. Thus, there is an increased risk of transmitting these viruses by pooling of plasma. However, the presence of justified limits for neutralising antibodies towards HAV and parvovirus B19 in the starting plasma and the final product, result in immune neutralisation and passive immunisation which both serve to limit or prevent virus replication in vivo and thereby infection in patients.

Five cases of possible transmission of vCJD, or the causative agent of this disease, by non-leukocyte-depleted red blood cell concentrates (n=4) and a low-purity coagulation factor concentrate to a haemophiliac (n=1) have been reported in the literature. The possibility of transmission of the vCJD agent by S/D plasma cannot be completely ruled-out. At present, the vCJD agent cannot be routinely detected in blood. However, the hypothesis of the B-lymphocytes and follicular dendritic cells, in particular, acting as a potential blood borne carriers of the prion protein and their role in neuroinvasion suggests that leukocyte depletion during processing of blood products and plasma derivatives will reduce the possibility of transmitting vCJD. Thus, leukocyte depletion of cellular blood components has been adopted by some countries as a measure to reduce the hypothetical risk of vCJD transmission. OCTAPLASMA undergoes multiple size exclusion filtration steps resulting in complete leukocyte removal without activating the leukocytes, and both this particular measure and the down-stream processing have demonstrated a potential to clear prions using an animal model of the agent causing vCJD. Additionally, a column has been included into the production process of OCTAPLASMA in order to specifically remove prions. This safety measure is considered effective for removing the infectious agent causing vCJD, if present in plasma. No animal material is used in the production of OCTAPLASMA.

Transmission of HAV may occur following transfusion with OCTAPLASMA. It is, however greatly reduced by accepting only plasma pools found negative for HAV by a NAT test and by the presence of neutralizing antibodies towards HAV (anti-HAV IgG with a minimum level of 0.6 IU/mL).

Transmission of parvovirus B19 may occur following transfusion of OCTAPLASMA. However plasma pools are tested for the presence of neutralizing antibodies towards parvovirus B19 (antiparvovirus B19 IgG with a minimum level of 11 IU/mL is acceptable) and the parvovirus B 19– NAT (an upper limit of 10.0 IU/μl is acceptable). This combination may limit the risk of infection, although no laboratory or clinical studies have been performed to show that it is sufficient to prevent infection. However, as with FFP, the transmission of parvovirus B19 or HAV by OCTAPLASMA cannot be totally excluded. In immunocompromised patients, in patients with haematological disorders of high red cell turnover and in pregnant women, parvovirus B19 infections could lead to aplastic crises and hydrops fetalis with subsequent foetal loss, respectively. Therefore, OCTAPLASMA should only be administered to these patients if strongly indicated. A possible risk of infection should be weighed against the benefit of the inactivation of enveloped viruses such as HIV, HBV and HCV. Appropriate vaccination (e.g. against HAV) for patients in regular receipt of OCTAPLASMA should be considered. Infusion of OCTAPLASMA may give rise to specific coagulation factor antibodies.

14 CLINICAL TRIALS

14.1 Trial Design and Study Demographics

Four clinical studies (Studies Nos. 1 to 4) and 8 post-authorisation studies (Studies Nos. 5 to 12) with OCTAPLASMA have been conducted by Octapharma. Two of the post-authorisation studies (Studies Nos. 11 to 12) have been conducted in 91 pediatric patients (age range 0-20 years). All these studies used an open design, which is an acceptable approach for a compound of this class.

14.2 Study Results

Based on the experience gathered during the clinical development phase and the post-marketing period, it can be concluded that OCTAPLASMA is efficacious and has a satisfying safety profile. In the 4 clinical studies (n=91 patients) a total of 6 AEs (in 4 patients) were assessed as related to OCTAPLASMA treatment.

Table 7 provides a comprehensive overview of clinical studies performed with OCTAPLASMA including those which were initiated as post-marketing studies.

Table 7: Overview of OCTAPLASMA clinical studies

Study No. Protocol No.	Number of Patients, Gender	Diagnosis, Inclusion / Exclusion Criteria	Treatment Dose Regimen	Evaluation Criteria	Results (Efficacy)	Results (Safety)
1	30 patients 21 male, 9 female	Intensive care patients with DIC requiring plasma therapy for the treatment of severe coagulopathy;	OCTAPLASMA, lyophilised, given i.v., mean dose 377 mL	PT, fibrinogen, ATIII, aPTT, PC, D-dimers; vital signs	PT, fibrinogen, antithrombin III increased significantly; aPTT, PC, D-dimers were not significantly different from baseline	No AEs;
2	11 patients 5 male, 6 female	Hereditary or acquired isolated or combined coag. factor deficiency;	OCTAPLASMA, lyophilised, given i.v., mean dose 580 mL;	Pharmacokinetics; stopping or prevention of bleeding; AE monitoring;	Overall efficacy rated as good in all patients;	3 AEs in 2 patients; no dropout due to AEs, no serious and/or unexpected AEs;
3 19/PLAS/I V/91	66 patients OCTAPLASMA: n=20 15 male, 5 female No plasma: n=26 FFP: n=20	Patients with open heart surgery requiring plasma therapy;	OCTAPLASMA, lyophilised, given i.v., mean dose 700 mL	Blood loss, coagulation and haematological lab parameters; AE monitoring	OCTAPLASMA and FFP comparable in terms of blood loss and coag. parameters	1 mild unrelated AE; no dropout due to AEs, no serious and/or unexpected AEs;
4 LAS-1-03-UK	55 patients OCTAPLASMA: n=30 18 male, 12 female FFP: n=25	Patients suffering from coagulopathy due to LD (n=24), LT (n=28) or TTP (n=3)	OCTAPLASMA, 200 mL bags given i.v. LD: mean dose 13 mL/kg; LT: mean dose 44 mL/kg TTP: up to 3 litres per day for 14 days;	Maintenance of coag. factors in LD and LT; platelet count in TTP; adverse vent monitoring;	PC, fibrinogen and PTT, prolonged INR improved in both groups; TTP patients attained platelet counts of > 50 x 10 ⁹ /l by day 10, and remained in stable remission 1 year later;	7 AEs in 5 patients; 2 AEs in 1 patient related to OCTAPLASMA; 2 deaths unrelated to study treatment during study period, 9 further deaths outside formal study period;

Study No. Protocol No.	Number of Patients, Gender	Diagnosis, Inclusion / Exclusion Criteria	Treatment Dose Regimen	Evaluation Criteria	Results (Efficacy)	Results (Safety)
5 LAS-1-02-D	67 patients OCTAPLASM A: n=36 FFP: n=31;	Intensive care patients following heart surgery requiring plasma therapy;	OCTAPLASMA 200 mL bags, given i.v.; total dose 600 mL; FFP 600 mL;	F1+2, PAP, D-dimers, PC, PT, aPTT, fibrinogen, FVIII; AT, PS, free PS and PI, TI; prophylaxis and stop of bleeds; AE monitoring; vital signs;	stat. significant differences in PS and PI after FFP compared to OCTAPLASMA; correlation between change of TI and change of PAP after 60 min. stat. significant for OCTAPLASMA; change of PI, and change of PAP after 60 min. stat. significant for FFP	No AEs or thrombotic complications during and after infusion of both products; 14 patients died during study (4 in OCTAPLASMA and 10 in FFP group); all cases not related to the trial drugs.
6 PVI/B001	OCTAPLASM A: n=894 age 8 days to 96 years; RBCC: n=11,749 platelet concentrate: n=1,711	Any patient requiring plasma therapy;	Plasma Viro-Inactivé (PVI) (=OCTAPLASMA), 200 mL bags; to be given i.v. according to physician's prescription;	AE monitoring;	(Not applicable)	No AEs for OCTAPLASMA; RBCC: 485 AEs; platelet concentrate: 142 AEs;
7 PVI/B002	55 neonates age 0 to 7 days;	Any patient requiring plasma therapy;	Plasma Viro-Inactivé (PVI) (=OCTAPLASMA), 200 mL bags; to be given i.v. acc. to physician's prescription;	AE monitoring;	(Not applicable)	No AEs;
8 PVI/B003	5 patients age 43 to 79 years, 2 males, 3 females	Rh-negative patients requiring plasma therapy irrespective of their anti-D status;	Plasma Viro-Inactivé (PVI) (=OCTAPLASMA), 200 mL bags; to be given i.v. acc. to physician's prescription;	Anti-D status at baseline and at weeks 1, 8, and 6 months after OCTAPLASMA administration;	No anti-D immunisation related to OCTAPLASMA administration;	No AEs;
9 PVI/B004	23 patients	Anti-HAV and/or anti-parvovirus B19 negative patients requiring plasma therapy;	Plasma Viro-Inactivé (PVI) (=OCTAPLASMA), 200 mL bags; to be given i.v. according to physician's prescription;	HAV IgG antibodies, HAV PCR, parvovirus B19 IgG antibodies, parvovirus B19 PCR;	HAV: In 14 patients evaluable passive immunisation against HAV; B19: in 4 out of the 9 patients evaluable for B19, passive immunisation;	HAV PCR during follow-up all negative; B19: in 1 patient seroconversion observed.

Study No. Protocol No.	Number of Patients, Gender	Diagnosis, Inclusion / Exclusion Criteria	Treatment Dose Regimen	Evaluation Criteria	Results (Efficacy)	Results (Safety)
10	Total: 610 adults and 198 children; OCTAPLASMA A: 119 adults and 63 children; Available for viral markers: n=343 (194 transfused)	Any patient with extracorporeal surgery;	OCTAPLASMA 200 mL bags, given i.v. acc. to physician's prescription, mean dose: 7.5 bags; other blood products: platelet concentrates, fresh whole blood, SAGMAN red cells;	Irregular red blood cell antibody screening; anti-HAV IgG, HBsAg, anti-HBc, anti-HCV IgG, anti-HIV-1/2, anti-HTLV IgG, anti-CMV IgG, anti-B19 IgG, PCR testing (HAV, B19).	(Not applicable)	No definite viral infections seen for OCTAPLASMA; no irregular antibodies;
11 LAS-212	50 patients (neonates /infants, children, adolescents) n=37 (0 to 2 years) n=13 (> 2 to 16 years)	Cardiac surgery (n=40), LT and/or with LD (n=5), sepsis-related coagulopathy (n=4) hypoxic encephalopathy (n=1)	OCTAPLASMA 200 mL bags Dose depended on the age and BW of the patient and on the clinical setting.	Safety assessment excellent, moderate or poor	INR, PT, aPTT, TEG or TEM within the expected ranges following use of OCTAPLASMA	Overall safety 'excellent' for all patients. No AEs, no hyperfibrinolytic events and no TEEs related to OCTAPLASMA
12 LAS-213	41 patients (children, adolescents) n=15 (2 to <12 years) n=13 (12 to <17 years) n=13 (≥17 to 20 years)	Immune system disorders (n=14), nervous system disorders (n=12), renal and urinary disorders (n=8), infections and infestations (n=4), and other (n=3)	1 to 6 TPEs per patient (mean 2.5), actual dose per TPE 4 mL/kg to 72 mL/kg (mean 28.6 mL/kg), mean total volume per TPE 1324.9 mL (range 113 mL – 4000 mL), mean infusion rate 0.32 mL/kg/min to 0.41 mL/kg/min	Monitoring of adverse drug reactions (drug-related TEs and TEEs), safety laboratory parameters (eg. ionized calcium), investigator's safety assessment	Due to the small sample size with different age groups, efficacy was not measured.	8 ADRs in 4 patients (citrate toxicity, headache, increased C-reactive protein, myalgia, nausea, pyrexia, and urticaria), no TE or TEEs, 7 ADRs mild, no drug-related SAEs, investigator's safety assessment: excellent for >90%

16 NON-CLINICAL TOXICOLOGY

OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) is a virus inactivated frozen human plasma and is assumed to be active on a species-specific basis. Human plasma may cause severe toxic reactions in animals and is not tolerated at dosages approaching those generally used in humans. Routine toxicology testing in laboratory animals is not considered to add any relevant information for the safety and efficacy of OCTAPLASMA in the clinical use. Therefore, no toxicological studies have been carried out in animals.

Studies were conducted to evaluate the effects of the materials used for viral inactivation by the S/D method. After purification, the maximum amounts of TNBP and Octoxynol in the finished product are 2.0 µg/mL and 5.0 µg/mL, respectively. Pharmacological and toxicological studies in animals indicate that these residual levels should present no clinical problem for the indications and dosages specified.

Based on preclinical data it is not possible to give information on the total quantity of OCTAPLASMA that can be administrated before any adverse effects of the S/D components are likely to become apparent.

However, "therapeutic windows" might be calculated for humans: according to acute intravenous toxicity tests in rats the lowest toxic sum dose of TNBP and Octoxynol (1:5) was 10,000 µg/kg. For a single dose of 20 mL/kg OCTAPLASMA containing < 140 µg/kg TNBP and Octoxynol at the ratio 2+5 this window is ≥ 71.4 .

- For a transfusion period of 5x20 mL/kg per day the window is ≥ 14.3 .
- For a 3-day treatment with 5x20 mL/kg per day the window is ≥ 4.8 .

These calculations, however, neglect the rapid metabolism of these compounds. As a consequence, greater safety margins might be assumed for repeated administration of OCTAPLASMA.

PATIENT MEDICATION INFORMATION

READ THIS FOR SAFE AND EFFECTIVE USE OF YOUR MEDICINE

OCTAPLASMA

Solvent detergent (S/D) treated human plasma

Read this carefully before you start taking OCTAPLASMA and each time you get a refill. This leaflet is a summary and will not tell you everything about this drug. Talk to your healthcare professional about your medical condition and treatment and ask if there is any new information about OCTAPLASMA.

Serious Warnings and Precautions

- This product is made from human plasma, which may contain infectious agents, such as viruses that cause hepatitis and other viral diseases. However, OCTAPLASMA is treated to either remove or inactivate certain viruses. Pathogen inactivation of lipid enveloped viruses such as HIV, HBV and HCV is achieved through solvent detergent (S/D) treatment of plasma and the production process also allows immune neutralization of non-lipid enveloped viruses such as HAV and Parvovirus B19. Your doctor should discuss the risks and benefits of this product with you before giving you this product.

What is OCTAPLASMA used for?

- Complex disorders of the blood clotting system due to severe liver failure, massive transfusion (this is the process of transferring blood or blood-based products from one person into the circulatory system of another), or repeated large volume plasma exchange. This is a removal procedure of (components of) blood plasma from the circulation (especially in patients with damaged liver function).
- OCTAPLASMA may be used for emergency therapy in clotting factor deficiencies, in special situations, e.g. when acute bleeding does not allow a precise laboratory diagnosis, or when a specific clotting factor concentrate is not available.
- Rapid conversion of the effects of oral anticoagulants (substances that prevent coagulation, i.e. they stop blood from clotting) when vitamin K is insufficient in emergency situations, or in patients with damaged liver function.

How does OCTAPLASMA work?

The administration of OCTAPLASMA can temporarily stop bleeding in patients with clotting factor deficiencies in emergency situations, when vitamin K treatment is insufficient, or in patients with damaged liver function. OCTAPLASMA will start working immediately upon injection and the symptoms of bleeding should resolve.

What are the ingredients in OCTAPLASMA?

Medicinal ingredients: Human plasma proteins

Non-medicinal ingredients: Glycine, Octoxynol, Sodium citrate dihydrate, Sodium dihydrogenphosphate dihydrate, TNBP

OCTAPLASMA comes in the following dosage forms:

OCTAPLASMA (Solvent Detergent (S/D) Treated Human Plasma) is supplied frozen in bags of 200 mL containing 45-70 mg/mL Human Plasma Proteins.

Do not use OCTAPLASMA if:

- IgA deficiency with documented antibodies against IgA
- Severe deficiency of protein S
- Hypersensitivity to this drug or to any ingredient

To help avoid side effects and ensure proper use, talk to your healthcare professional before you take OCTAPLASMA. Talk about any health conditions or problems you may have, including if you:

- You recently had a heart attack, have a high risk of blood clots, or have coronary artery disease.
- If you have fluid in the lungs or cardiac failure.
- If you have IgA deficiency.
- If you had previous reactions to plasma proteins, fresh frozen plasma or OCTAPLASMA.
- If you are pregnant or nursing. A pregnancy test is recommended before receiving OCTAPLASMA.
- You have a disease that causes marked fibrinolysis that is responsible for breaking down blood clots.

Tell your healthcare professional about all the medicines you take, including any drugs, vitamins, minerals, natural supplements or alternative medicines.

The following may interact with OCTAPLASMA:

- There is no known drug interaction to OCTAPLASMA. OCTAPLASMA administration may slow the protection of live attenuated vaccines such as measles, mumps, rubella (also known as three-day or liberty measles) and chicken pox for at least six weeks, and possibly up to three months or longer.

How to take OCTAPLASMA:

- OCTAPLASMA will be given to you by a healthcare professional in a healthcare setting.

Usual dose:

The dose you receive will depend on your clinical situation and disease, but 12-15 mL OCTAPLASMA/kg body weight is a generally accepted starting dose. The duration of administration will be determined by your doctor.

Overdose:

Overdose may lead to volume overload and thereby water in the lung and/or heart failure. In such cases, OCTAPLASMA transfusion should be stopped immediately.

If you think you, or a person you are caring for, have taken too much OCTAPLASMA, contact a healthcare professional, hospital emergency department, or regional poison control centre immediately, even if there are no symptoms.

Missed Dose:

Not applicable because OCTAPLASMA is usually given in a hospital setting.

What are possible side effects from using OCTAPLASMA?

Side effects may include:

- Nausea, flushing, hives, fast heart rate, drop in blood pressure, reduction or cessation of breathing, and reduction or cessation of a sufficient amount of blood flow from the heart throughout the body that may result in impaired function of internal organs.
- In the course of plasma exchange, symptoms attributable to citrate overdose (e.g. fatigue, a sensation of tingling, numbness or prickling, tremor and low calcium concentrations) may occur.
- Acute lung injury, a syndrome known as transfusion related acute lung injury, may occur and is characterized by chills, fever, a non-productive cough, and difficulty or shortness of breath.
- Passive post-transfusion purpura (PTP) may occur which is characterized by difficulty or shortness of breath, rash, fever, discoloration of the skin that may include a reddish purple to brown color and marked reduction in platelets.

These are not all the possible side effects you may have when taking OCTAPLASMA. If you experience any side effects not listed here, tell your healthcare professional.

If you have a troublesome symptom or side effect that is not listed here or becomes bad enough to interfere with your daily activities, tell your healthcare professional.

Reporting Side Effects

You can report any suspected side effects associated with the use of health products to Health Canada by:

- Visiting the Web page on Adverse Reaction Reporting (<https://www.canada.ca/en/health-canada/services/drugs-health-products/medeffect-canada.html>) for information on how to report online, by mail or by fax; or
- Calling toll-free at 1-866-234-2345.

NOTE: Contact your health professional if you need information about how to manage your side effects. The Canada Vigilance Program does not provide medical advice.

Storage:

Store frozen at < -18 °C, protect from exposure to light. After thawing, OCTAPLASMA can be stored for up to 5 days at +2-8 °C or for up to 8 hours at room temperature (+20-25°C) before use. Thawed OCTAPLASMA must not be refrozen. Unused product must be discarded.

Keep out of reach and sight of children.

If you want more information about OCTAPLASMA:

- Talk to your healthcare professional
- Find the full product monograph that is prepared for healthcare professionals and includes this Patient Medication Information by visiting the Health Canada website: (<https://www.canada.ca/en/health-canada/services/drugs-health-products/drug-products/drug-product-database.html>); the manufacturer's website <http://www.octapharma.ca>, or by calling 1-888-438-0488.
